Programming Methodology

Lab 10: Asynchronous Programming

Wednesday, November 8th, 2023

Weekly Lab Agenda

- Go over reminders/goals
- Review past material
- Work in groups of 2-3 to solve a few exercises
- Discussion leaders will walk around and answer questions
- Solutions to exercises will be reviewed as a class
- Attendance taken at the end

Reminders

- Homework 6 is due tonight at 11:59pm
    - Come to office hours for help!
- Get in touch with your team for HW7 if you haven't already!
- HW7 is due Tuesday, November 21st at 6pm.

Today's Goals

- Practice working with asynchronous programming

Promises: then()

`Promise.prototype.then(onFulfill, onReject)` (onReject is optional)

- When the promise resolves (fulfilled/rejected), the corresponding handler is called
  - argument passed to `onFulfill` is *fulfillment value*
  - argument passed to `onReject` is *rejection reason*

Promises: then()

`.then(...)` returns a new `Promise, p`

If the handler returns (the function passed to `.then()`):

- **A *value***: `p` gets fulfilled with the value
- **A *pending promise, a***: the resolution of `p` is subsequent to the resolution of `a`
  - If `a` fulfills, then `p` fulfills with the same value
  - If `a` rejects, then `p` rejects with the same value
- **A *resolved promise***: `p` is fulfilled/rejected with the resolved `Promise`'s fulfillment/rejection value respectively

Promises: resolve(), reject(), catch()

`Promise.resolve(value)`: “resolves” a value to a Promise
    if value is a Promise, value is returned
    otherwise, resolve returns a Promise fulfilled with that value

`Promise.reject(reason)`: returns a Promise that is rejected with a given reason.
    Best practice: reason is an Error for debugging and error catching

`Promise.prototype.catch(onReject)`:
    p.catch(onReject) is the same as p.then(undefined, onReject)
    (no handler for fulfill, just for reject)

Promises: all(), any(), race()

`Promise.all(promiseArr)`: returns a Promise that asynchronously:

- fulfills when all promises in the array fulfill (or when promiseArr is empty)
- rejects when any of the promises rejects, with the first reject reason

`Promise.any(promiseArr)`: returns a Promise that asynchronously:

- fulfills when any promise in the array fulfills, with its fulfillment value
- rejects when all of the promises reject (or when promiseArr is empty), with an AggregateError of the reject reasons

`Promise.race(promiseArr)`: returns a Promise that settles with the eventual state of the first Promise in promiseArr that settles

`Promise.allSettled(promiseArr)`: returns a Promise that always fulfills with an array of objects describing the outcome of each input promise:

```
{ status: "fulfilled" | "rejected", value?: someType, reason?: errType }
```

Exercise 1: Promises

Write a function getObjsWithName that takes in an array of URLs and returns a promise of an array of objects. The array of objects should contain all objects with the property “name” found at every URL that points to JSON data.

Assume (1) All urls point to valid JSON data.
(2) Assume the data is an array of objects.

Hint: You may use “in” to check properties

Exercise 1: Promises

Write a function getObjsWithName that takes in an array of URLs and returns a promise of an array of objects. The array of objects should contain all objects with the property “name” found at every URL that points to JSON data.

fetch() will return a promise, which may resolve or reject
=> we get an array of Promises

Use response.json() to get JSON representation of the GET response.
=> json() returns a Promise

Exercise 1: Promises

… returns a Promise of an array of objects. The array of objects should contain all objects with the property “name” found at every URL that points to JSON data.

Wrap result in Promise.allsettled.

=> Call to Promise.allsettled always fulfills with an array of objects.

```
{ status: "fulfilled" | "rejected", value?: someType, reason?: errType }
```

Use filter and in to check if object has property `name`.

For each url, we have an of array of objects with “name” property

Need to combine results from all urls into one, i.e, go from Object[ ][ ]⇒ Object[ ]

=> flatten the result into a single array using flat()

Testing your function (included with starter code)

Write a function getObjsWithName that takes in an array of URLs and returns returns a promise of an array of objects. The array of objects should contain all objects with the property “name” found at every URL.

```
const urls: string[] = ['https://api.github.com/users/umass-compsci-220/repos',
'https://api.github.com/users/umass-cs-230/repos'];

//Printing the “name” property of objects
getObjsWithName(urls)
.then(obs => obs.map(obj => obj["name"]))
.then(console.log);
```

"huffman_project"]
```

Exercise 2: Compose Functions

Write a function that takes an array of **asynchronous** functions and returns a function that is their composition.

```
Example: Composition of 3 synchronous functions
composeFunctions([f, g, h])
    Composition of functions is a function: (x) => h(g(f(x)))
    Apply first function to the input f(x)
    Apply second function to the result of the first g(f(x))
     Apply third function to the result of the second h(g(f(x)))
```

Exercise 2: Compose Functions

Write a function that takes an array of **asynchronous** functions and returns a function that is their composition.

Exercise asks composition of asynchronous functions.
=> each function takes in a value and returns a Promise.

The returned function should compose the functions in the array, applying them successively, left to right, and return a promise that resolves to the result or rejects with the reason of the first promise that rejects.

```
Example: Composition of 3 asynchronous functions
composeFunctionsAsync([f, g, h])
    (x) => f(x).then(g).then(h)
    where f(x) returns a Promise
    then apply g to its fulfillment value, and produce another Promise
    then apply h to that fulfillment value, and produce a Promise with the result
```

Testing your function (included with starter code)

```
let getJSON = composeFunctionsAsync([fetch,
              (fetchres :Response) => fetchres.ok ? fetchres.json():Promise.reject("Error with fetching")])

//Print the first objects "owner" property?
getJSON('https://api.github.com/users/umass-cs-230/repos').then(res => res[0]["owner"]).then(console.log);
```
